## 3. Task Recognition

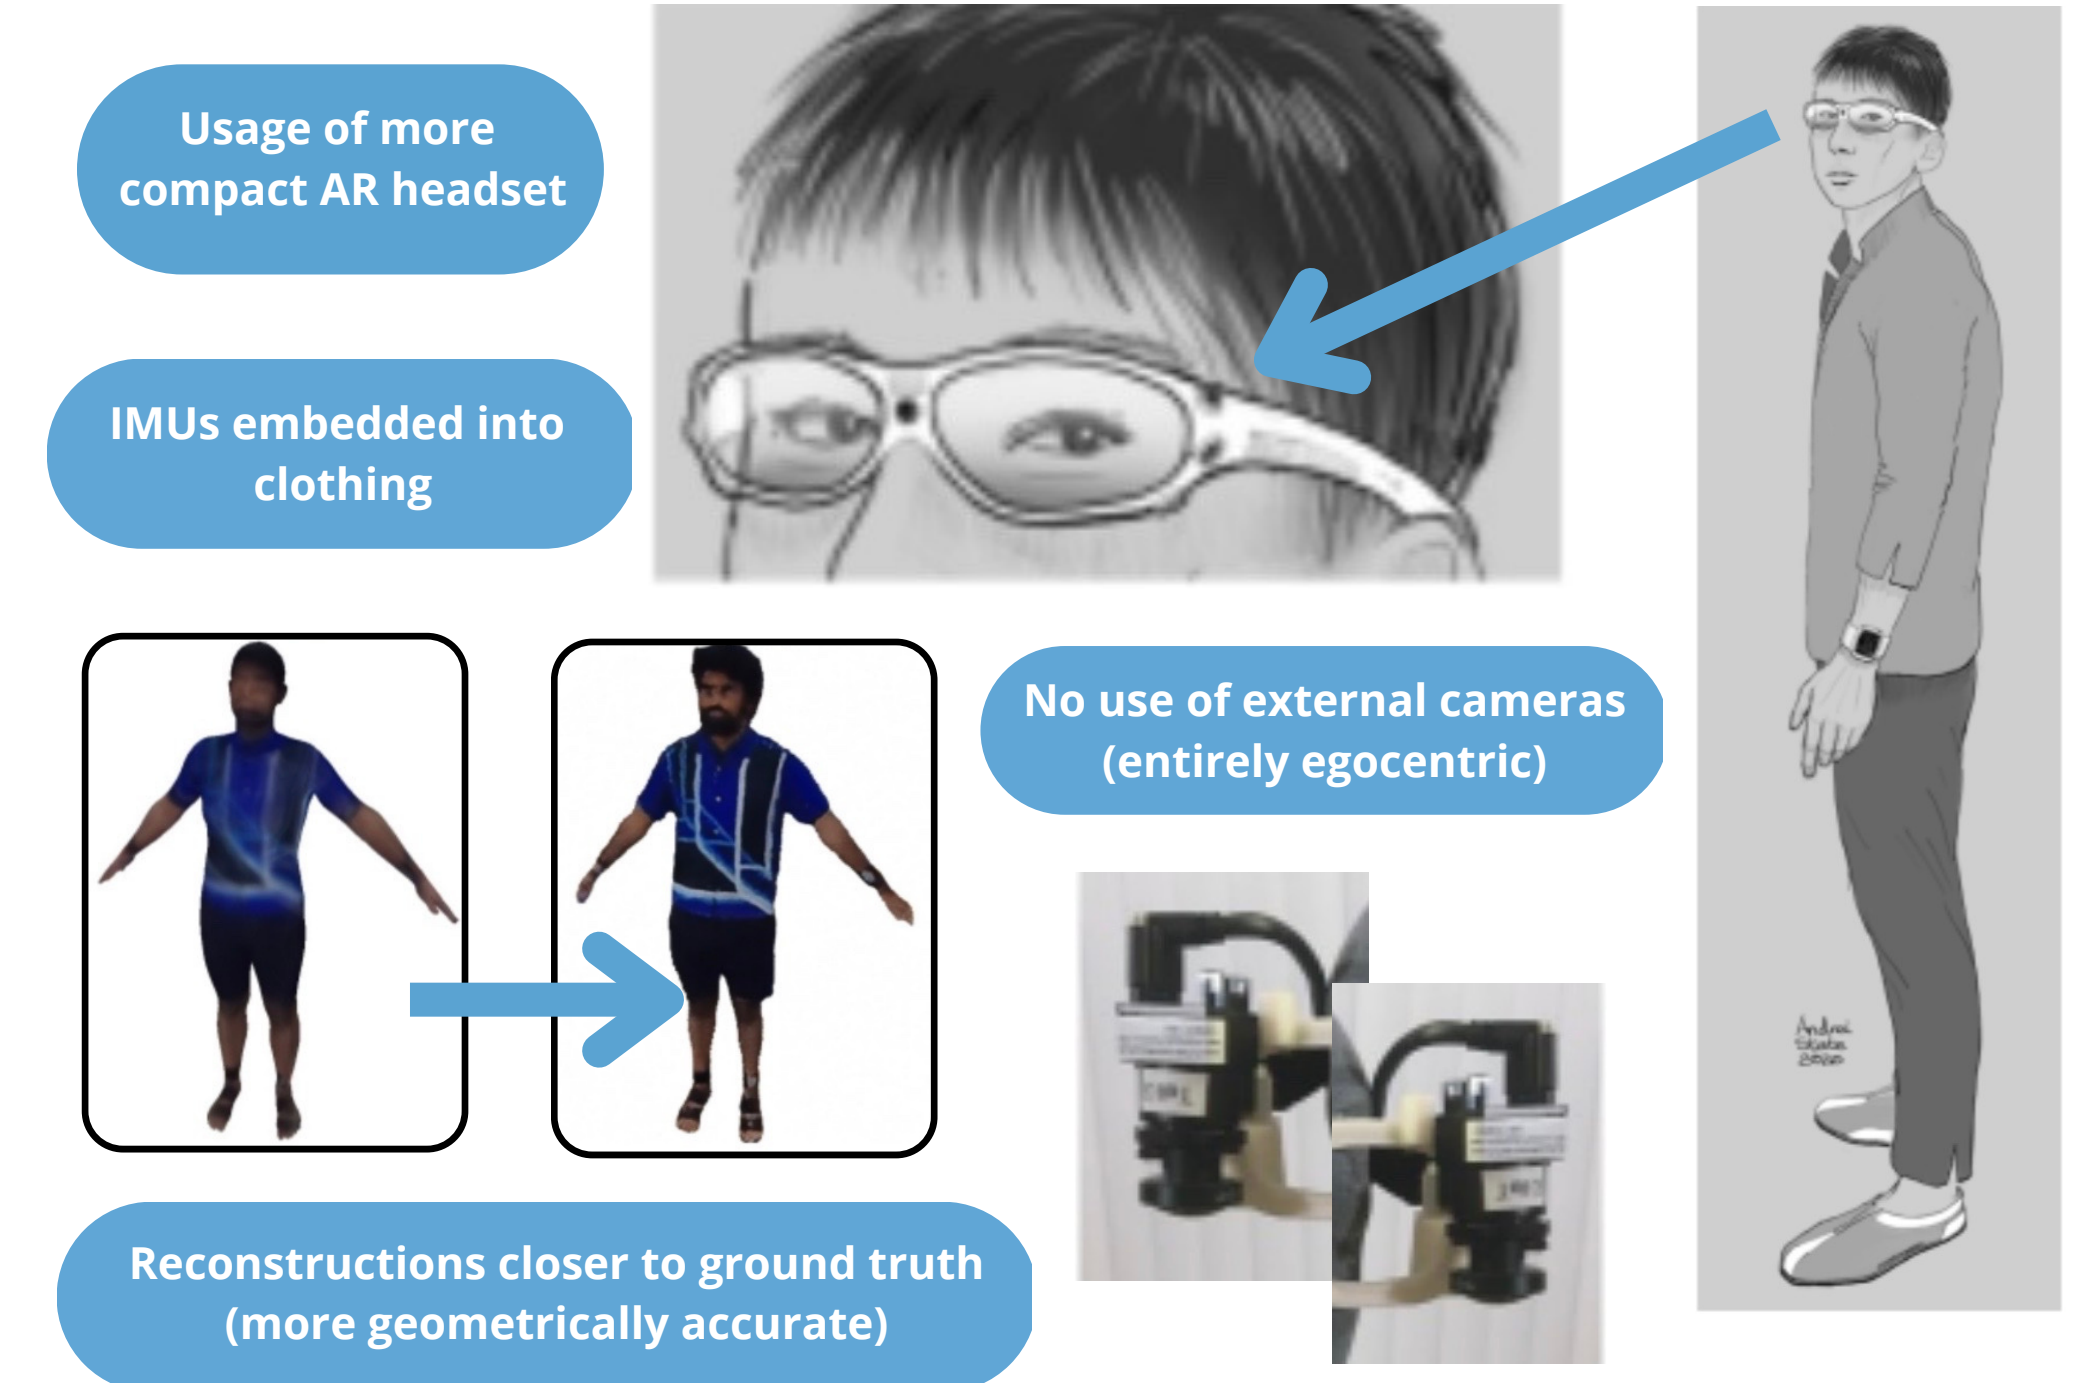

## Motivations

## Introduction

## Future Goals

Our system aims to improve clinician decision-making and outcomes for individuals with PD undergoing augmented reality (AR)-based neurorehabilitation. Currently, our focus is on collecting, constructing, and presenting a given patient's ADL data to clinicians and care partners via a head-mounted display (HMD). This system's pipeline encompasses 4 main steps: **collecting data**, using said data for **patient reconstruction** in a virtual environment, **recognizing patient's ADLs**, and presenting interactive **visualizations** of said ADLs to clinicians and care partners. Future iterations of our system will address additional neurorehabilitation goals (i.e. enhancing clinical visits and at-home patient exercises).
